| Sample Type | : Serum - 13593158 | | |

BIOCHEMISTRY

| Name | Results | Unit | Bio. Ref. Interval |
|--|---------|--------|--------------------|
| ELECTROLYTE PROFILE (SODIUM,POTASSIUM,CHLORIDE) | | | |
| DIUM ,Serum Methodology: ISE | 137.5 | mmol/L | 135-150 |
| POTASSIUM ,Serum Methodology: ISE | 5.45 | mmol/L | 3.5-5.5 |
| CHLORIDE ,Serum Methodology: ISE | 108.60 | mmol/L | 94 - 110 |

CLINICAL NOTES

Electrolytes are minerals that are found in body tissues and blood in the form of dissolved salts. As electrically charged particles, electrolytes help move nutrients into and out of the body's cells, maintain a healthy water balance, and help stabilize the body's acid/base (pH) level.

Sodium - most of the body's sodium is found in the fluid outside of the body's cells, where it helps to regulate the amount of water in the body.

Potassium - this electrolyte is found mainly inside the body's cells. A small but vital amount of potassium is found in the plasma, the liquid portion of the blood. It plays an important role in regulating muscle contraction. Monitoring potassium is important as small changes in the potassium level can affect the heart's rhythm and ability to contract.

Chloride - this electrolyte moves in and out of the cells to help maintain electrical neutrality (concentrations of positively charged cations and negatively charged anions be equal) and its level usually mirrors that of sodium. Due to its close association with sodium, chloride also helps to regulate the distribution of water in the body.

MARK

Haemolysis caused by the release of potassium from as few as 0.5% of the erythrocytes (from specimen collection) can increase the serum level of potassium by 0.5 mEq/L.

Haemolysis shows no significant interference to sodium or chloride.

Severe hyponatremia may be seen with lipemic specimens as a result of fluid displacement.

In very rare cases gammopathy, in particular type IgM (Waldenström's macroglobulinemia), may cause unreliable results.
